Abstract

For a mixing and uniformly expanding interval map $f : I \rightarrow I$ we pose the following questions. For which permutation transformations $\sigma : I \rightarrow I$ is the composition $\sigma \circ f$ again mixing? When $\sigma \circ f$ is mixing, how does the mixing rate of $\sigma \circ f$ typically compare with that of $f$?

As a case study, we focus on the family of maps $f(x) = mx \mod 1$ for $2 \leq m \in \mathbb{N}$. We split $[0,1)$ into $N$ equal subintervals, and take $\sigma$ to be a permutation of these. We analyse those $\sigma \in S_N$ for which $\sigma \circ f$ is mixing, and show that, for large $N$, typical permutations will preserve the mixing property. In contrast to the situation for continuous time diffusive systems, we find that composition with a permutation cannot improve the mixing rate, but may make it worse. We obtain a precise result on the worst mixing rate which can occur as $\sigma$ varies, with $m, N$ fixed and $\gcd(m, N) = 1$.

1 Introduction

We consider a mixing dynamical system $(f, I, \mu)$, where $f : I \rightarrow I$ is an ergodic $\mu$-measure preserving transformation on a compact interval $I$. If we divide the interval $I$ up into $N$ equal subintervals, we also consider a permutation transformation $\sigma : I \rightarrow I$ formed by permuting these $N$ subintervals. The question we consider is the following: is the composition $\sigma \circ f$ still mixing for general permutations $\sigma$? If mixing is preserved then does the mixing rate of $\sigma \circ f$, typically increase (or decrease) relative to applying $f$ alone? The physical motivation for studying this kind of problem arises through studies of mixing rates for diffusive systems, see [2]. In this work, it is shown that the rate of mixing in a one dimensional, continuous time diffusive system can be accelerated by applying a permutation transformation at regular time steps $t \in \mathbb{N}$. Thus we consider this question when diffusive systems are replaced by uniformly expanding maps, which in themselves are regularly considered as canonical examples of mixing protocols [14].

A more general problem would be to consider mixing (and non-uniformly expanding) systems $f : M \rightarrow M$, with $M$ a compact set, and compose $f$ with a
piecewise isometric map $T : M \to M$. We can then ask if $T \circ f$ is typically mixing, and moreover, when $T \circ f$ is mixing does the mixing rate (typically) increase or decrease? Typical here, would mean that if $f$ or $T$ belong to some (parametrized) family of maps, then mixing is preserved for a generic (or full measure) set of parameters. Ergodic and topological properties of these kind of transformations (e.g. maps of the form $x \mapsto \beta x + \alpha \mod 1$, $0 < \alpha < 1 < \beta$) have been studied, see for example [8, 11]. Permutation groups also feature more generally in the study of combinatorial dynamical systems [11], and in the study of topological entropy [4].

In this article we investigate the family of maps $f(x) = mx \mod 1$, for $2 \leq m \in \mathbb{N}$, $x \in [0, 1]$ and take $\sigma$ to be a permutation transformation on $[0, 1]$. Thus we regard $\sigma$ as an element of the symmetric group $S_N$, which consists of all permutations of $N$ symbols and has order $\#S_N = N!$. Individually, $f$ and $\sigma$ are well understood in terms of their dynamical properties, but their composition $\sigma \circ f$ is not. It therefore becomes an interesting group theoretic and combinatorial problem to determine when $\sigma \circ f$ is mixing. Thus the first problem we consider is how to classify those permutations $\sigma \in S_N$ for which $\sigma \circ f$ is mixing (or not mixing). We will show that if $N$ is not a multiple of $m$ then $\sigma \circ f$ is mixing for all permutations $\sigma \in S_N$. This will be the focus of Theorem 1. In contrast, when $N$ is a multiple of $m$, we will show that there exist permutations in $S_N$ for which $\sigma \circ f$ is not mixing, but asymptotically (as $N \to \infty$) the proportion of such permutations tends to zero. This will be the focus of Theorem 2 and Theorem 3.

In the case where $\sigma \circ f$ is mixing, we then calculate (or estimate) the rate of mixing using spectral methods, see [3, 13, 18, 20]. We will give an overview of the relevant theory in Section 3. In particular, we will work with the Perron-Frobenius operator $L_{\sigma \circ f}$ restricted to the space of functions of bounded variation (BV) and calculate its eigenvalues. This operator is not compact on BV, but it does have a spectral gap. We will show that the essential spectral radius is precisely $1/m$, and use a Fredholm matrix approach to calculate the remaining (isolated) eigenvalues. The modulus of the largest of these eigenvalues in the interior of the unit circle gives the (exponential) mixing rate of $\sigma \circ f$. We analyse how these isolated eigenvalues vary with the permutation $\sigma$. This can be done directly, but the complexity of the calculation increases rapidly as $m, N$ grow. Thus we use linear algebra and combinatorial methods to find/estimate the largest eigenvalues of $L_{\sigma \circ f}$ (with modulus less than one). In particular, while $f$ itself has mixing rate $1/m$, we will show in Theorem 4 that if $\gcd(N, m) = 1$ and $N > m$, then the worst mixing rate for $\sigma \circ f$ as $\sigma$ varies is $|\sin(\pi m/N)/(m \sin(\pi/N))|$. This value can be made arbitrarily close to one by taking $N$ large. The proof of Theorem 4 involves an investigation of the eigenvalues of certain doubly stochastic matrices, and, in particular, the effect on the eigenvalues of permuting the columns of the matrix. Although the determination of the eigenvalues of various classes of stochastic matrices is an old problem which has been considered by a number of authors (see for instance [5, 6, 10, 12, 22]), we give a fairly simple result in this direction (Lemma 8.4) which seems to be new and may perhaps be of independent interest.

While the above results are for the specific family of maps $f(x) = mx \mod 1$, we also consider two further examples, where different behaviours occur. In Section 7, we give a piecewise linear Markov map $f : [0, 1] \to [0, 1]$, such that $\sigma \circ f$ is not mixing
for a positive asymptotic proportion of permutations $\sigma \in S_N$. The proof is purely combinatorial. We also give an example in Section 3.6 to show that, at least for certain non-uniformly expanding maps $f$, the composition with permutations can (typically) speed up the rate of mixing. This will happen if $f$ has a well defined source that inhibits the mixing, such as a map with intermittent behaviour [9, 15]. Heuristically, the mixing rate of $\sigma \circ f$ will be faster than that of $f$ if the permutation action removes the intermittent source.

2 Mixing versus non-mixing

In this section we state our results in relation to the question of mixing versus non-mixing of $\sigma \circ f$. Given a measure preserving system $(f, M, \mu)$, we say that the system is (strongly) mixing if

$$|\mu(f^{-n}A \cap B) - \mu(A)\mu(B)| \to 0 \text{ as } n \to \infty,$$

where $A, B$ are $\mu$-measurable sets. Another version of mixing is that of topological mixing, namely we say $(f, M)$ is topologically mixing if for all open $U, V \subset M$, there exists a constant $n_0(U, V)$ such that $\forall n \geq n_0$, $f^n(U) \cap V \neq \emptyset$. To show that $f$ is not mixing, then it is usually easier to show that $f$ is not topologically mixing. We will take this approach when exhibiting maps $f$ and $T$ such that $f$ is mixing, but $T \circ f$ is not mixing. For the examples that we consider, it will be also true that topological mixing implies strong mixing, see [20] and Section 3.

To be more precise we consider certain piecewise expanding maps $f$ on the unit interval. We divide the unit interval into equal subintervals, and compose $f$ with permutations of these. To avoid the problem of functions being undefined, or multiply defined, at endpoints of these subintervals, we work with (non-compact) intervals which are closed on the left and open on the right. Thus we consider piecewise continuous maps $f: [0, 1) \to [0, 1)$. We can of course regard $f$ as a map on the compact interval $[0, 1]$ (by stipulating $f(1) = f(0)$) or on the circle $S^1 = \mathbb{R}/\mathbb{Z}$.

We divide the unit interval as follows. Fix $N \geq 2$, and let $I_j = [j/N, (j + 1)/N)$, $0 \leq j < N$. For any permutation $\sigma$ of $\{0, 1, \ldots, N - 1\}$ we write $\sigma$ also for the corresponding interval exchange map:

$$\sigma(x) = x + (\sigma(j) - j)/N \mod 1 \text{ for } x \in I_j.$$

We identify the indexing set $\{0, \ldots, N - 1\}$ with the the ring $\mathbb{Z}/N\mathbb{Z}$ of integers modulo $N$, so that arithmetic in this indexing set is to be interpreted as arithmetic modulo $N$, and we write $S_N$ for the group of all permutations of $\mathbb{Z}/N\mathbb{Z}$.

The specific map $f: [0, 1) \to [0, 1)$ we consider is $f(x) = mx \mod 1$ for a fixed integer $m \geq 2$. Our goal is then to investigate those permutations $\sigma \in S_N$ for which the composite piecewise linear function $g = \sigma \circ f$ on $[0, 1)$ fails to be (topologically) mixing.

When $N$ is not a multiple of $m$, the result is easy to state.

**Theorem 1** In the above situation, suppose that $N$ is not a multiple of $m$. Then, for every $\sigma \in S_N$, the composite $g = \sigma \circ f$ is mixing.
This leaves us with the case $N = m\ell$ for some integer $\ell$. In this case, we shall give a combinatorial characterisation of those $\sigma$ for which $\sigma \circ f$ is not mixing. In order to state the result, we first introduce some terminology. We consider partitions $\mathbb{Z}/N\mathbb{Z}$ into disjoint non-empty sets: $\mathbb{Z}/N\mathbb{Z} = A_1 \cup \ldots \cup A_t$. We call the set $\mathcal{B} = \{A_1, \ldots, A_t\}$ of subsets of $\mathbb{Z}/N\mathbb{Z}$ a block decomposition of $\mathbb{Z}/N\mathbb{Z}$, and refer to the $A_i$ as blocks. We say that $\mathcal{B}$ is trivial if $t = 1$, and that $\mathcal{B}$ is $\ell$-stable if, for any $j \in \mathbb{Z}/N\mathbb{Z}$ and $1 \leq r \leq t$, we have $j \in A_r \Rightarrow j + \ell \in A_r$. Thus $\mathcal{B}$ is $\ell$-stable if and only if each $A_r$ is a union of cosets of the subgroup $\ell \mathbb{Z}/N\mathbb{Z}$ of $\mathbb{Z}/N\mathbb{Z}$. If $\mathcal{B} = \{A_1, \ldots, A_t\}$ is a block decomposition and $\sigma \in S_N$, then $\sigma \mathcal{B} = \{\sigma(A_1), \ldots, \sigma(A_t)\}$ is also a block decomposition, and we define the stabiliser $G_\mathcal{B}$ of $\mathcal{B}$ as

$$G_\mathcal{B} = \{\sigma \in S_N : \sigma(\mathcal{B}) = \mathcal{B}\}.$$ 

Then $G_\mathcal{B}$ is a subgroup of $S_N$.

**Theorem 2** Let $f(x) = mx \mod 1$ and let $N = m\ell$. There is a permutation $\delta \in S_N$ such that the following holds: for any $\sigma \in S_N$, the composite $g = \sigma \circ f$ fails to be mixing if and only if there is some nontrivial $\ell$-stable block decomposition $\mathcal{B}$ of $\mathbb{Z}/N\mathbb{Z}$ such that $\sigma \delta \in G_\mathcal{B}$.

We will use this combinatorial result to investigate the proportion

$$p(\ell, m) = \frac{\sharp\{\sigma \in S_{m\ell} : \sigma \circ f \text{ is not mixing}\}}{(m\ell)!}$$

(2)

of permutations for which $g = \sigma \circ f$ fails to be mixing. (Here and subsequently, we write $\sharp X$ to denote the cardinality of a finite set $X$.) In Section 5 we will obtain explicit formulae for $p(\ell, m)$ when $\ell$ is small, while in Section 6 we prove the following upper bound:

**Theorem 3** When $N = m\ell$ with $\ell \geq 6$, we have

$$p(\ell, m) < 11 \left(\frac{2e}{\ell}\right)^{m-1}.$$ 

In particular, for each fixed $m \geq 2$ we have $p(\ell, m) \to 0$ as $\ell \to \infty$.

This may be interpreted as saying that $\sigma \circ f$ is mixing for almost all permutations $\sigma$ when $N$ is large enough. Since $\sigma$ typically preserves the property of mixing, it is then natural to study the mixing rate of $\sigma \circ f$ relative to that of $f$ alone.

### 3 Rates of mixing under permutation action

For the map $f(x) = mx \mod 1$, $m \geq 2$, and for general $\sigma \in S_N$ we consider the rate of mixing of the composed transformation $\sigma \circ f$. For specific $\sigma \in S_N$ we will calculate explicit estimates on the rate of mixing, and show that permutations will either preserve the rate of mixing or slow the mixing rate down relative to the transformation $\text{Id} \circ f$. 

(where \( \text{Id} \) is the identity). For the latter case, we will show that for given \( m \), there exist permutation transformations that give rise to arbitrarily slow (exponential) mixing rates. In the other direction, we also discuss briefly the case when \( f \) is a non-uniformly expanding map with a well defined source that gives rise to the non-uniform expansion. We will show in this case, that composing a permutation transformation with \( f \) will typically speed up the mixing rate.

3.1 Background on transfer operators and Fredholm matrices

Our methods for studying mixing rates will utilize the theory of transfer operators and Fredholm matrices, see [3, 13, 16, 18, 20]. We now give an overview of the relevant theory. For a measure preserving system \((f, M, \mu)\), the rate of mixing can be quantified in various ways. However, we will primarily focus on the speed of convergence to equilibrium. More precisely, if \( f: [0, 1] \to [0, 1] \) is a piecewise expanding map, we define the Perron-Frobenius operator \( \mathcal{L}_f: L^1 \to L^1 \) by:

\[
\{ \mathcal{L}_f \phi \}(x) = \sum_{f(y)=x} \frac{\phi(y)}{f'(y)}, \quad \forall \phi \in L^1.
\]

The operator \( \mathcal{L}_f \) satisfies the following identity, for \( \phi \in L^p, \psi \in L^q \) (with \( p^{-1} + q^{-1} = 1 \)):

\[
\int (\mathcal{L}_f \phi) \psi \, dx = \int \phi(\psi \circ f) \, dx,
\]

where \( dx \) denotes integration with respect to the reference (Lebesgue) measure. If \( f \) preserves an ergodic measure \( \mu \) with density \( \rho(x) \in L^1 \), then \( (\mathcal{L}_f \rho)(x) = \rho(x) \). Suppose now that we have a Banach space \( B \subset L^1 \), with \( \rho \in B \), and with norm \( \| \cdot \|_B \). We define the speed of convergence to equilibrium in \( B \) as the rate \( r(n) \) such that there exists \( C_B < \infty \),

\[
\| \mathcal{L}_f^n \phi - \rho \|_B \leq C_B r(n), \quad \forall \phi \in B, \| \phi \|_1 = 1, \forall n \geq 1,
\]

and there exists \( \phi \in B \) with \( \| \phi \|_1 = 1 \), such that (for sufficiently large \( n \)) and for some \( C_\phi > 0 \)

\[
\| \mathcal{L}_f^n \phi - \rho \|_B \geq C_\phi r(n), \quad \forall \phi \in B.
\]

For the whole space \( L^1 \), the rate function \( r(n) \) cannot be specified, i.e. there exist \( \phi \in L^1 \) for which \( \| \mathcal{L}_f^n \phi - \rho \|_1 \) decays arbitrarily slowly. When \( f \) is a piecewise expanding map, the natural space to consider is \( B = BV \), the class of functions with bounded variation. We recall this definition as follows, see [13]. Given a function \( \phi: [0, 1] \to \mathbb{R} \), we define the total variation of \( \phi \) as

\[
\text{var}(\phi) = \sup \left\{ \sum_{k=1}^n |\phi(x_k) - \phi(x_{k-1})| : 0 \leq x_0 \leq \ldots \leq x_n = 1 \right\},
\]

where the sup is taken over all partitions of \([0, 1]\). We say that \( \phi \) has bounded variation (i.e. \( \phi \in BV \)) if \( \text{var}(\phi) < \infty \). To make BV into a Banach space, we define the norm \( \| \cdot \|_{BV} \) by

\[
\| \phi \|_{BV} := \| \phi \|_1 + \text{var}(\phi),
\]

5
and hence consider functions \( \phi \in BV \) with \( \| \phi \|_{BV} < \infty \). Bounds on the rate of mixing \( r(n) \) can then be obtained by analysing the spectral properties of the restriction \( \mathcal{L}_f|_{BV}: BV \to BV \). In particular we say that \( \mathcal{L}_f|_{BV} \) has a spectral gap if

\[
\tau := \sup \{|\lambda| : \lambda \in \text{Spec}(\mathcal{L}_f|_{BV}) \setminus \{1\}\} < 1, \tag{8}\]

where \( \text{Spec}(\mathcal{L}_f) \) is the spectrum of \( \mathcal{L}_f \). Hence for any \( \phi \in BV \) and any \( \epsilon > 0 \), the spectral decomposition of \( \mathcal{L}_f|_{BV} \) implies that there exists \( C > 0 \) such that for all \( n \),

\[
||\mathcal{L}_f^n(\phi) - \rho||_{BV} \leq C \cdot (\tau + \epsilon)^n \|\phi\|_{BV} \text{ with } \|\phi\|_1 = 1. \tag{9}\]

Thus \( \tau \) determines the rate of convergence to equilibrium. In general, finding the exact value of \( \tau \) is not straightforward. We can, however, consider the essential spectral radius, \( r_{ess}(\mathcal{L}_f|_{BV}) \), and this is defined by

\[
r_{ess}(\mathcal{L}_f|_{BV}) := \inf\{r \geq 0 : \lambda \in \text{Spec}(\mathcal{L}_f|_{BV}), |\lambda| > r \implies \lambda \text{ isolated}\}. \tag{10}\]

In the above definition of \( r_{ess} \), the isolated eigenvalues \( \lambda \) with \( |\lambda| > r \) are also of finite multiplicity. For piecewise expanding maps, see [13, Theorem 1], we have the lower bound on \( \tau \) via

\[
\tau \geq r_{ess} = \exp \left\{ -\liminf_{k \to \infty} \inf_{x \in [0,1]} \frac{1}{k} \log |(f^k)'(x)| \right\}. \tag{11}\]

This lower bound will be strict if there are no isolated eigenvalues with modulus in \((r_{ess}, 1)\). To study upper bounds on the speed of convergence to equilibrium we will need to determine the location (or existence) of these isolated eigenvalues. We will use a Fredholm matrix approach for Markov dynamical systems, see [16, 17]. A summary is as follows.

Consider a piecewise linear Markov map \( f : I \to I \), with finite partition \( \mathcal{P} = \{I_i\}_{i=1}^q \), and representative transition matrix \( B \). Here \( B \) is a \( q \times q \) matrix with \( B_{ij} = 1 \) if \( I_j \subset f(I_i) \), and \( B_{ij} = 0 \) if \( f(I_i) \cap I_j = \emptyset \). We will assume that \( f \) is differentiable on the interior of each element of \( \mathcal{P} \). If \( \mathcal{L}_f \) is the Perron-Frobenius operator, and \( J \subset I \), we consider the power series defined on \( \mathbb{C} \times D \), with \( D \subset \mathbb{C} \):

\[
s^J(z, x) = \sum_{n=0}^{\infty} z^n \mathcal{L}_f^n(\chi_J)(x) = \chi_J(x) + \sum_{n=1}^{\infty} z^n \mathcal{L}_f^n(\chi_J)(x), \tag{12}\]

where \( \chi_J(x) \) is the indicator function of \( J \). When \( J = I_i \in \mathcal{P} \), we will write \( s^J(z, x) \) as \( s^{(i)}(z, x) \). We let \( s(z, x) \) be the vector \( (s^{(i)}(z, x))_{i=1}^q \), and similarly \( \chi(x) = (\chi_{(i)}(x))_{i=1}^q \). For a Markov system we have the following result.

**Proposition 3.2** For a piecewise linear Markov map \( f : I \to I \) with finite partition \( \mathcal{P} = \{I_i\}_{i=1}^q \), there exists a \( q \times q \) matrix \( \Phi(z) \), and such that

\[
s(z, x) = (I - \Phi(z))^{-1} \chi(x). \tag{13}\]
The matrix $\Phi(z)$ in Proposition 3.2 is called a Fredholm matrix.

Proof. We will consider the Markov case where the slope is constant on each $I_i$ (but not constant globally). Our proof is a slight adaption of the calculations in [16, 17]. In particular we will obtain an explicit form of $\Phi(z)$. First of all, by definition of $\mathcal{L}_f$ we have

$$s^J(z, x) = \mathcal{X}_f(x) + \sum_{n=1}^{\infty} z^n \sum_{f^n(y) = x} \mathcal{X}_f(y) \frac{\mathcal{X}_f(y)}{(f^n)'(y)}.$$ 

If $J = I_i \in \mathcal{P}$, the following hold:

$$s^{(i)}(z, x) = \mathcal{X}_{(i)}(x) + z \sum_{n=1}^{\infty} \sum_{f^{n-1}(f(y)) = x} \frac{\mathcal{X}_{(i)}(y)}{|(f^{n-1})'(f(y))|}$$

$$= \mathcal{X}_{(i)}(x) + z \sum_{n=1}^{\infty} \sum_{f^{n-1}(y) = x} \sum_{b_{i,j} = 1} \frac{\mathcal{X}_{(i)}(y)}{|(f^{n-1})'(y)|}$$

$$= \mathcal{X}_{(i)}(x) + \left( \frac{z}{|(f'| I_i)|} \sum_j B_{ij} \right) s^{(j)}(z, x).$$

Hence we obtain a $q \times q$ matrix $\Phi(z)$, with $\Phi(z)_{ij} = \{z/|(f' | I_i)|\} B_{ij}$, and

$$s(z, x) = (I - \Phi(z))^{-1} \mathcal{X}(x).$$ (13)

This completes the proof. 

Given the Fredholm matrix $\Phi(z)$, we define the Fredholm determinant to be the quantity $D(z) = \det(I - \Phi(z))$. For piecewise-linear expanding (Markov) systems, the Fredholm matrix and Fredholm determinant have the following properties, see [16, 17]:

1. The number of ergodic components of $f$ is equal to the dimension of the eigenspace of $I - \Phi(1)$ associated to the eigenvalue of value zero. The number of ergodic components is also equal to the order of the zero at $z = 1$ in the equation $\det(I - \Phi(z)) = 0$.

2. If zero is a simple eigenvalue of $I - \Phi(1)$ then the system is ergodic. Moreover if $\{|z| = 1\} \cap \text{Spec}(\mathcal{L}_f|_{BV}) = \{1\}$ then the system is mixing.

3. If $\lambda \in \mathbb{C}$ and $|\lambda| > r_{ess}$, then $\lambda \in \text{Spec}(\mathcal{L}_f|_{BV})$ if and only if $z = \lambda^{-1}$ is a zero of $D(z)$, i.e. $D(1/\lambda) = 0$.

4. If $D(1/\lambda) = 0$ then $\lambda$ is an eigenvalue of $\mathcal{L}_f|_{BV}$.

In addition, the (ergodic) invariant density $\rho(x)$ can also be computed, and is given by the following formula:

$$\rho(x) = \sum_i \frac{v_i}{\sum_j |I_j| v_j} \mathcal{X}_{(i)}(x),$$ (14)
where \( \mathbf{v} = \{ v_i \}_{i=1}^q \) is a left-eigenvector of \( \Phi(1) \) associated to eigenvalue 1. i.e. \( \sum_i v_i \Phi(1)_{i,j} = v_j \). The proof of equation (14) is quite straightforward, i.e. just check that \( (\mathcal{L}_f\rho)(x) = \rho(x) \). Thus, the Fredholm matrix \( \Phi(z) \) at \( z = 1 \) can viewed as the dual operator to \( \mathcal{L}_f \) (relative to the vector space generated by the indicator functions on the Markov partition \( \mathcal{P} \)).

**Connection with decay of correlations.**

Instead of considering the speed of convergence to equilibrium a related quantity is that of decay of correlations \([3, 16, 20]\). Given a Banach space \( \mathcal{B} \), we say that \((f, M, \mu)\) has decay of correlations in \( \mathcal{B} \) with rate function \( r(n) \) if there exists some \( C_{\mathcal{B}} \) such that

\[
\forall \phi, \psi \in \mathcal{B} \text{ with } ||\phi|| = ||\psi|| = 1, \quad C_n(\phi, \psi, \mu) := \left| \int \phi(\psi \circ f^n) d\mu - \int \phi d\mu \int \psi d\mu \right| \leq C_{\mathcal{B}} r(n). \tag{15}
\]

When \( \psi \in L^\infty \) and \( f \in \text{BV} \), then we have

\[
C_n(\phi, \psi, \mu) \leq ||\psi \rho||_\infty ||\mathcal{L}_f^n(\phi \rho) - \rho||_1 \leq ||\psi \rho||_\infty ||\mathcal{L}_f^n(\phi \rho) - \rho||_{\text{BV}} \tag{16}
\]

where in the last step we use \( || \cdot ||_1 \leq || \cdot ||_{\text{BV}} \). Hence the rate of decay of correlations depends on the eigenvalues of \( \mathcal{L}_f|_{\text{BV}} \). i.e. we have that \( \forall \epsilon > 0: \)

\[
\lim_{n \to \infty} (|\lambda| + \epsilon)^{-n} C(\phi, \psi, \mu) = 0, \quad \lambda^{-1} = \inf\{z : z^{-1} \in \text{Spec}(\mathcal{L}_f|_{\text{BV}}) \setminus \{1\}\}. \tag{17}
\]

**Connection with dynamical zeta functions**

It can be further shown that the Fredholm determinant \( D(z) \) (for a piecewise linear, (Markov) expanding system) is related to the dynamical zeta function \( \zeta(z) \) via:

\[
\zeta(z) = \frac{1}{D(z)} \text{ where, } \zeta(z) = \exp \left\{ \sum_{n=1}^\infty \frac{z^n}{n} \sum_{p \cdot f^n(p) = p} \frac{1}{(f^n)'(p)} \right\}, \tag{18}
\]

see \([3, 16]\) for an overview. Thus, within the region \( |z| > r_{\text{ess}} \), \( \zeta(z) \) is meromorphic with singularities (poles) at the zeros of \( D(z) \). In particular \( \zeta(z) \) is analytic in the region \( |z| < r_{\text{ess}} \).

To see the relationship between \( \zeta(z) \) and \( D(z) \), the Fredholm determinant can be calculated as:

\[
\det \{(I - \Phi(z))^{-1}\} = \exp \{ -\text{tr} \log(I - \Phi(z)) \} = \exp \left\{ \sum_{n=1}^\infty \frac{1}{n} \text{tr}(\Phi(z)^n) \right\},
\]

where \( \text{tr} \) is the trace operation. If, for example \( \Phi(z) = \frac{1}{m} B \), where \( f' \mid I_i = m \) for all \( I \in \mathcal{P} \), then

\[
\det(I - \Phi(z))^{-1} = \exp \left\{ \sum_{n=1}^\infty \frac{z^n}{n} \cdot \frac{\text{tr}(B^n)}{m^n} \right\},
\]

and \( \text{tr}(B^n) \) is precisely the number of fixed points of \( f^n \).
3.3 Statement of results

In our setting we consider specifically the map \( f(x) = mx \mod 1 \). When \( f \) is composed with a permutation \( \sigma \in S_N \), the resulting piecewise linear transformation may or may not be mixing, as discussed in Section 2. Here, we focus on those transformations that are mixing, but we consider now the rate of mixing. We state the following result.

**Theorem 4** Fix \( m, N \geq 2 \) and consider the transformations \( \sigma \circ f \) where \( f(x) = mx \mod 1 \) and \( \sigma \in S_N \). Then the following hold.

1. For all \( \sigma \in S_N \), the essential spectral radius is given by \( r_{\text{ess}}(L_{\sigma \circ f}|_{BV}) = 1/m \).
2. When \( \gcd(m,N) = 1 \), we have
   \[
   \max\{ |\lambda| : \lambda \in \text{Spec}(L_{\sigma \circ f}|_{BV}), |\lambda| \neq 1, \sigma \in S_N \} = \frac{\sin(\pi m/N)}{m \sin(\pi/N)}.
   \] (19)

   This value therefore gives the worst mixing rate as \( \sigma \) varies over \( S_N \).

**Remark 3.4** Notice that for fixed \( m \) and taking \( N \) sufficiently large, Theorem 4 implies the existence of eigenvalues of \( L_{\sigma \circ f}|_{BV} \) arbitrarily close to one: for the maximal eigenvalue \( \lambda \) in equation (19), we have \( |\lambda| \sim 1 - \pi^2(m^2 - 1)/(6N^2) + o(1/N^2) \).

Thus, the results obtained here are contrary to the results obtained when considering permutation actions applied to diffusive systems, as described in [2]. In that setting, the mixing rate is always observed to increase when permutation actions are applied at fixed time steps, while in our setting, the permutation actions will either preserve the mixing rate or slow it down.

The proof of Theorem 4 in particular Statement 2, is given in Section 8. The computation of \( r_{\text{ess}} \) is straightforward since \( \sigma \circ f \) is piecewise linear with constant slope \( 1/m \). Hence Statement 1 is a consequence of [13]. To find upper estimates on the mixing rates it suffices to compute or estimate the eigenvalues of the Fredholm matrix associated to \( \sigma \circ f \) for a particular permutation \( \sigma \). This will utilize techniques in linear algebra and the combinatorics associated to permutation matrices. When \( f(x) = mx \mod 1 \), and \( \sigma \) is the identity permutation, an elementary calculation implies that the Fredholm matrix \( \Phi(1) \) has eigenvalues equal to zero (multiplicity \( m - 1 \)) and one. Here we take the natural Markov partition of \( \sigma \circ f \) by dividing up the unit interval into \( m \) equal subintervals.

Let us now consider some explicit examples and make some further observations, some of which are based on numerical computations. For each \( \sigma \in S_N \), we are interested in the quantity

\[
\Lambda_\sigma = \max\{ |\lambda| : \lambda \in \text{Spec}(L_{\sigma \circ f}|_{BV}), |\lambda| \neq 1 \}.
\]

This gives the mixing rate for \( \sigma \circ f \), so that in particular, composition with \( \sigma \) decelerates the mixing if and only if \( \Lambda_\sigma > 1/m \). For small values of \( m \) and \( N \), Table 1 summarizes the number of permutations in \( S_N \) which this occurs. This suggests that as we increase \( N \) (with \( m \) fixed), we should expect a higher proportion of permutations in \( S_N \) to decelerate the mixing. We therefore pose the following question:
Question 3.5 Is it the case that
\[
\lim_{N \to \infty} \frac{\sharp\{\sigma \in S_N : \Lambda_\sigma > 1/m\}}{N!} = 1?
\]
To investigate this further, we fixed values \( m = 2, 3 \) and chose 1000 permutations at random from \( S_N \) for \( N \) large. We then examined the proportions of these permutations for which \(|\lambda_\sigma(m)| > 1/m\). Table 2 summarizes the results.

More generally, it would be interesting to know the distribution of \( \Lambda_\sigma \) as \( \sigma \) varies (with \( N \) large). As in [5], one might expect this to be well approximated by a generalised extreme value distribution with parameters depending on \( N \).

### 3.6 Speeding up mixing for non-uniformly expanding systems

Although we have shown that permutations cannot speed up the mixing rates for certain uniformly expanding systems, we will demonstrate here that permutations can speed up the rate of mixing if the original (un-permuted) system has a well-defined source that inhibits mixing. Consider the following family of intermittency maps \( f_\alpha : [0, 1] \to [0, 1], \alpha \in (0, 1) \) given by

\[
f_\alpha(x) = \begin{cases} x(1 + 2^\alpha x^\alpha) & \text{if } x \in [0, 1/2], \\ 2x - 1 & \text{if } x \in (1/2, 1]. \end{cases}
\]

This family has been widely studied [15, 21] and optimal decay of correlations/speed of convergence to equilibrium has been established in [9]. In particular, it is shown that there exists a Banach space \( \mathcal{B} \), such that

\[
||\mathcal{L}_n^\alpha(\phi) - \rho||_\mathcal{B} \leq Cn^{-\frac{1}{\alpha}}||\varphi||_\mathcal{B},
\]
for all $\phi \in \mathcal{B}$ with $\|\phi\|_1 = 1$. Moreover this asymptotic in $n$ is optimal within $\mathcal{B}$. The sub-exponential mixing rate arises since each $f_\alpha$ admits a neutral fixed point at $x = 0$, namely $f'(0) = 1$. The existence of the neutral fixed point inhibits the mixing. In particular, the functional analytic methods discussed in Section 3.1 do not apply since $\{\lambda = 1\}$ is no longer an isolated eigenvalue of $L_f$, i.e. there is no spectral gap.

If we consider $f_\alpha$ composed with a permutation $\sigma \in S_N$, then typical permutations will destroy the neutral fixed point. i.e. $\sigma \circ f_\alpha$ will be uniformly expanding if $\sigma$ does not leave invariant the interval $[0, 1/N]$. We state the following.

**Theorem 5** Suppose $f_\alpha$ is given by equation (20), and $\sigma \in S_N$ is a permutation transformation on $[0, 1]$ that does not leave $[0, 1/N]$ invariant. Suppose that $\sigma \circ f$ is topologically mixing. Then, in $\mathcal{B} = \text{BV}$, we have an exponential rate of convergence to equilibrium: $\exists C > 0$, $\eta \in (0, 1)$, such that, for all probability distributions $\phi \in \mathcal{B}$,

$$||L^n_{\sigma \circ f}(\phi) - \rho||_{\text{BV}} \leq C\eta^n \cdot ||\phi||_{\mathcal{B}}, \quad (22)$$

**Proof.** Since $\sigma$ does not preserve $[0, 1/N]$, the map $\sigma \circ f$ is uniformly expanding on $[0, 1]$. In general the map is not Markov (with respect to a finite partition), but it does have bounded variation on $[0, 1]$. Thus if $\sigma \circ f$ is topologically mixing, then it follows from [13, 20] that $\sigma \circ f$ has absolutely continuous invariant measure, with density in BV. Since the system is uniformly expanding, the operator $L_{\sigma \circ f}$ now has a spectral gap. Thus the rate of convergence to equilibrium is now exponentially fast. \hfill \blacksquare

**Remark 3.7** Since $\sigma \circ f_\alpha$ is no longer Markov, a complete analysis of which permutations preserve topological mixing is a much harder problem, which we do not pursue.

### 4 When is $\sigma \circ f$ non-mixing?

In this section, we prove Theorems 1 and 2. Recall that we are considering the composite $g = \sigma \circ f$ where $f(x) = mx \mod 1$ and $\sigma \in S_N$, and that we partition the unit interval into subintervals $I_a = [a/N, (a + 1)/N)$ for $a \in \{0, 1, \ldots, N - 1\}$, where this indexing set is identified with the ring $\mathbb{Z}/N\mathbb{Z}$ of integers modulo $N$.

To begin with, we allow arbitrary $m$, $N \geq 2$.

**Definition 4.1** For any subset $A \subseteq \mathbb{Z}/N\mathbb{Z}$, we define

$$\tilde{f}(A) = \bigcup_{d=0}^{m-1} (mA + d) \subseteq \mathbb{Z}/N\mathbb{Z}, \quad \tilde{g}(A) = \sigma(\tilde{f}(A)).$$

**Proposition 4.2** For each $A \subseteq \mathbb{Z}/N\mathbb{Z}$, we have

$$f\left(\bigcup_{a \in A} I_a\right) = \bigcup_{b \in \tilde{f}(A)} I_b, \quad g\left(\bigcup_{a \in A} I_a\right) = \bigcup_{b \in \tilde{g}(A)} I_b.$$
Proof. This is immediate since for each \( j \in \mathbb{Z}/N\mathbb{Z} \) we have
\[
f(I_j) = \bigcup_{d=0}^{m-1} I_{mj+d}, \quad \sigma(I_j) = I_{\sigma(j)}.
\]

Proposition 4.3 For each \( A \subseteq \mathbb{Z}/N\mathbb{Z} \), we have
\[
\sharp A \leq \sharp \tilde{f}(A) \leq m\sharp A.
\]
Moreover, suppose that \( 0 < \sharp A < N \). Then we have \( \sharp \tilde{f}(A) = \sharp A \) if and only if the following two conditions hold:

(i) \( N = ml \) for some integer \( l \);

(ii) \( A \) is a union of cosets of \( l\mathbb{Z}/N\mathbb{Z} \) (that is, \( j \in A \Rightarrow j + l \in A \) for all \( j \in \mathbb{Z}/N\mathbb{Z} \)).

Proof. If \( b \in \tilde{f}(A) \) then \( b \equiv ma + d \) (mod \( N \)) for at least one of the \( m\sharp A \) pairs \((a,d)\) with \( a \in A \) and \( 0 \leq d < m \). Hence \( \sharp \tilde{f}(A) \leq m\sharp A \). Now fix one pair \((a_0,d_0)\). If another pair \((a,d)\) gives the same element \( b \) then
\[
ma + d \equiv ma_0 + d_0 \pmod{N}.
\]

Thus \( d \equiv d_0 \pmod{s} \), where \( s = \gcd(m,N) \). This gives \( m/s \) possibilities for \( d \). For each of these, \((23)\) has \( s \) solutions \( a \) in \( \mathbb{Z}/N\mathbb{Z} \), all congruent \( \pmod{N/s} \) (but in general not all in \( A \)). So each \( b \) arises from at most \( m \) of the pairs \((a,d)\), giving \( \sharp \tilde{f}(A) \geq \sharp A \). This proves the first assertion.

If \( \sharp \tilde{f}(A) = \sharp A \), then each \( b \) must arise from exactly \( m \) pairs \((a,d)\). Thus given \( a_0 \in A \), we may take \( d = d_0 = 0 \), and the \( s \) solutions \( a \) to \((23)\) must all lie in \( A \). This shows that \( a_0 + N/s \in A \), so that \( A \) is stable under addition of \( N/s \).

First suppose (i) holds. Then \( N/s = l \), so that if \( \sharp \tilde{f}(A) = \sharp A \) then (ii) holds. Conversely, if (i) and (ii) hold, then each \( b \in \tilde{f}(A) \) arises from \( m \) pairs \((a+jl,d)\) with \( 0 \leq j < m \), so that \( \sharp \tilde{f}(A) = \sharp A \).

It remains to show that if (i) does not hold and \( \sharp \tilde{f}(A) = \sharp A > 0 \) then \( A = \mathbb{Z}/N\mathbb{Z} \). So let \( m = es \) with \( e > 1 \), and let \( a_0 \in A \). Since \( s < m \), we may take \( d_0 = s \) in \((23)\). But \((23)\) must have \( s \) solutions for each of the possible values \( d \equiv d_0 \pmod{s} \) with \( 0 \leq d < m \), so we can find \( a_1 \in A \) with \( ma_1 \equiv ma_0 + s \) (mod \( N \)). Then \( ea_1 \equiv ea_0 + 1 \) (mod \( N/s \)). Iterating, we can find \( a_j \in A \) with \( ea_j \equiv ea_{j-1} + 1 \equiv ea_0 + j \) (mod \( N/s \)) for \( j \geq 1 \). As \( \gcd(e,N/s) = 1 \), we have \( a_\infty \equiv a_0 + 1 \) (mod \( N/s \)). Since we already know that \( A \) is stable under addition of \( N/s \), it follows that \( A \) is stable under addition of 1, so that \( A = \mathbb{Z}/N\mathbb{Z} \).

Corollary 4.4 For any \( A \subseteq \mathbb{Z}/N\mathbb{Z} \), we have
\[
\sharp \tilde{g}(A) \geq \sharp A.
\]
Moreover, if \( A \) is a proper subset of \( \mathbb{Z}/N\mathbb{Z} \) then equality can only occur if \( N = \ell m \) for some integer \( \ell \).
Proposition 4.6 There exists a permutation \( \delta \).

Proof. This is clear since \( \tilde{g}(A) = \tilde{f}(A) \). ■

Lemma 4.5 \( g \) fails to be (topologically) mixing if and only if there is some proper subset \( A \) of \( \mathbb{Z}/N\mathbb{Z} \) such that \( \tilde{g}^r(A) = \tilde{z}A \) for all \( r \geq 0 \).

Proof. Let \( A \) be a subset with \( 0 < \tilde{z}A < N \) and \( \tilde{g}^r(A) = \tilde{z}A \) for all \( r \). As there are only finitely many subsets of \( \mathbb{Z}/N\mathbb{Z} \), we may choose \( s \geq 0 \) and \( t \geq 1 \) with \( \tilde{g}^{s+t}(A) = \tilde{g}^s(A) \).

Set \( B = \tilde{g}^s(A) \) and take nonempty open sets \( U \subseteq I_j \) and \( V \subseteq I_k \) where \( j \in B \) and \( k \notin B \). Then for all \( n \geq 0 \) we have \( g^n(U) \subseteq \bigcup_{b \in B} I_b \) so that \( g^n(U) \cap V = \emptyset \). Hence \( g \) is not mixing.

Conversely, suppose there is no proper subset \( A \) with \( \tilde{g}^r(A) = \tilde{z}A \) for all \( r \). To see that \( g \) is mixing, we show that for any nonempty open subset \( U \) of \( [0, 1] \) we have \( g^n(U) = [0, 1] \) for large enough \( n \). Without loss of generality, \( U \) is an interval of length \( \delta > 0 \). Since \( m > 1 \), we can choose \( h \) large enough that \( g^h(U) \) contains the initial point \( j/N \) of some interval \( I_j \). Then for some \( \epsilon > 0 \), we have \( [j/N, j/N + \epsilon] \subseteq g^h(U) \cap I_j \).

Choose \( k \) so that \( m^k \epsilon > 1/N \) and let \( g^k(j/N) = j'/N \). Then \( I_{j'} \subseteq g^k(I_j) \subseteq g^{h+k}(U) \).

Now let \( B = \{ j' \} \) and take \( s \geq 0 \), \( t \geq 1 \) with \( \tilde{g}^{s+t}(B) = \tilde{g}^s(B) \). The nonempty set \( A = \tilde{g}^s(B) \) then satisfies the condition \( \tilde{g}^n(A) = A \) for all \( n \geq 0 \). Hence, by Corollary 4.4, we have \( \tilde{g}^r(A) = \tilde{z}A \) for all \( r \geq 0 \). Thus our hypothesis forces \( A = \mathbb{Z}/N\mathbb{Z} \), so that \( \tilde{g}^q(I_{j'}) = [0, 1] \) for all \( q \geq s \). It follows that \( g^n(U) = [0, 1] \) for all \( n \geq h + k + s \), as required. ■

Proof of Theorem 7 Suppose that \( N \) is not a multiple of \( m \), and let \( g = \sigma \circ f \) with \( \sigma \in S_N \). By Corollary 4.4 there is no proper subset \( A \) with \( \tilde{g}(A) = \tilde{z}A \). Hence by Lemma 4.3 \( g \) is mixing. ■

We now suppose that the \( N = ml \) for some integer \( \ell \geq 1 \).

Proposition 4.6 There exists a permutation \( \delta \in S_N \) such that
\[
f(I_j) \supseteq I_{\delta(j)} \quad \text{for all } j \in \mathbb{Z}/N\mathbb{Z}.
\]

For any such \( \delta \), and any \( A \subseteq \mathbb{Z}/N\mathbb{Z} \), the following are equivalent:

(i) \( \tilde{g}(A) = \tilde{z}A \);

(ii) \( A \) is a union of cosets of the subgroup \( \ell\mathbb{Z}/N\mathbb{Z} \) of \( \mathbb{Z}/N\mathbb{Z} \);

(iii) \( \sigma \delta(A) = \tilde{g}(A) \).

Proof. To prove the first assertion, we exhibit a permutation \( \delta \) with the required property. For \( 0 \leq i < N \), write \( i = j + \ell t \) with \( 0 \leq c < m \) and \( 0 \leq j < \ell \), and set \( \delta(i) = mj + c \). It is routine to verify that \( \delta \in S_N \), and, as
\[
f(I_j) = \bigcup_{d=0}^{m-1} I_{mj+d},
\]
We continue to assume \((\ref{eq:24})\) holds.

Now fix a choice of \(\delta \in S_N\) satisfying \((\ref{eq:24})\). Since \(\tilde{z}g(A) = \tilde{z}f(A)\), the equivalence of (i) and (ii) follows from Proposition \((\ref{prop:1.3})\). Since \(\sigma \delta \in S_N\), it is immediate that (iii) \(\Rightarrow\) (i). It remains to show that (ii) \(\Rightarrow\) (iii).

Since \(f(I_j) = f(I_{j+\ell})\) for each \(j\), it follows from \((\ref{eq:24})\) that \(\delta\) takes the \(m\) elements \(j + cl, 0 \leq c < m\) to the \(m\) elements \(mj + d, 0 \leq d < m\) in some order. Thus, if (ii) holds, \(\delta\) takes each coset \(a + \ell \mathbb{Z}/N\mathbb{Z}\) contained in \(A\) to \(f(\{a\})\). Thus \(\delta(A) = \tilde{f}(A)\), and applying \(\sigma\) gives (iii).

**Proof of Theorem \((\ref{thm:2})\).** Let \(\sigma \delta \in G_B\) for some nontrivial, \(\ell\)-stable block decomposition \(B\), and let \(A\) be a block of \(B\). Then \(A\) is a proper subset of \(\mathbb{Z}/N\mathbb{Z}\) which is a union of cosets of \(\ell \mathbb{Z}/N\mathbb{Z}\). Thus \(\tilde{g}(A) = \sigma \delta(A)\) by Proposition \((\ref{prop:4.6})\) and this set is also a block of \(B\). Inductively, we then have \(\tilde{g}^r(A) = (\sigma \delta)^r(A)\), and hence \(\tilde{z}g^r(A) = z(\sigma \delta)^r(A) = zA\), for all \(r \geq 0\). It then follows from Lemma \((\ref{lem:4.5})\) that \(g\) is non-mixing.

Conversely, suppose that \(g\) is non-mixing. By Lemma \((\ref{lem:4.5})\), there is a proper subset \(A\) of \(\mathbb{Z}/N\mathbb{Z}\) such that \(\tilde{z}g^r(A) = \tilde{z}A\) for all \(r \geq 0\). By Proposition \((\ref{prop:4.6})\) and induction, \(\tilde{g}^r(A) = (\sigma \delta)^r(A)\) for all \(r \geq 0\). Moreover, each \((\sigma \delta)^r(A)\) is a union of cosets of \(\ell \mathbb{Z}/N\mathbb{Z}\). Since \(\sigma \delta\) is a permutation, it follows that \((\sigma \delta)^s(A^c)\) is also a union of cosets for each \(s \geq 0\), where \(A^c\) is the complement of \(A\). Let \(\tilde{B}\) be set of all intersections of the sets \((\sigma \delta)^r(A), (\sigma \delta)^s(A^c)\) for \(r, s \geq 0\). Thus \(\tilde{B}\) is a collection of subsets of \(\mathbb{Z}/N\mathbb{Z}\), each of which is a union of cosets of \(\mathbb{Z}/N\mathbb{Z}\). Let \(B\) be the collection of minimal nonempty sets in \(\tilde{B}\). Then \(B\) is an \(\ell\)-stable block decomposition and \(\sigma \delta \in G_B\). Moreover, \(B\) is nontrivial since \(A\) is a union of blocks of \(B\).

**Remark 4.7** A similar argument shows that \(f \circ \sigma\) is non-mixing if and only if \(\delta \sigma \in G_B\) for some nontrivial \(\ell\)-stable block decomposition.

## 5 The Proportion of Non-mixing Permutations

We continue to assume \(N = m \ell\). We shall investigate the proportion \(p(\ell, m)\) of permutations \(\sigma \in S_N\) for which \(g = \sigma \circ f\) is not mixing. By Theorem \((\ref{thm:2})\) this is the proportion of permutations such that \(\delta \sigma\) is in the stabiliser of at least one nontrivial \(\ell\)-stable block decomposition. For small values of \(\ell\), we can use the Inclusion-Exclusion Principle (see e.g. \([14]\) p. 21) to count the number of such permutations directly. We will also give the precise asymptotic behaviour of \(p(\ell, m)\) as \(m \to \infty\) with \(\ell\) fixed. In the next section, we give an asymptotic upper bound for \(p(\ell, m)\) as \(\ell \to \infty\) with \(m\) fixed, thereby proving Theorem \((\ref{thm:3})\).

The stabiliser of any nontrivial \(\ell\)-stable block decomposition contains the subgroup 
\(H \cong S_m \times \ldots \times S_m\) of order \((m!)^\ell\) which permutes the \(m\) elements of each coset amongst themselves. It will be convenient to calculate the index of \(H\) in the various stabilisers we consider, and to express these in terms of multinomial coefficients. For integers \(r_1, \ldots, r_j \geq 0\), the corresponding multinomial coefficient is 
\[
\binom{s}{r_1, \ldots, r_j} = \frac{s!}{r_1! \ldots r_j!}
\]
where \( s = r_1 + \cdots + r_j \). This counts the number of ways of putting \( s \) labeled objects into \( j \) labeled boxes, so that, for \( 1 \leq i \leq j \), box \( i \) contains \( r_i \) objects. When \( j = 2 \), the multinomial coefficient reduces to the more familiar binomial coefficient.

In order to refer to specific block decompositions, we let \( C_1, \ldots, C_\ell \) denote the cosets of \( \ell \mathbb{Z}/N\mathbb{Z} \) in \( \mathbb{Z}/N\mathbb{Z} \) (in some order). Giving an \( \ell \)-stable block decomposition amounts to giving a partition of \( \{C_1, \ldots, C_\ell\} \), and we denote the block decomposition by the corresponding partition of the set of indices \( \{1, \ldots, \ell\} \). Thus \( \{1, \ldots, \ell - 1\}, \{\ell\} \) represents the \( \ell \)-stable block decomposition consisting of the two blocks \( C_1 \cup \ldots \cup C_{\ell-1} \) of size \( (\ell - 1)m \) and \( C_\ell \) of size \( m \).

### 5.1 \( \ell = 1 \)

The only \( \ell \)-stable block decomposition is the trivial one, so \( g = \sigma \circ f \) is mixing for all \( \sigma \), and \( p(1, m) = 1 \).

### 5.2 \( \ell = 2 \)

There is only one nontrivial \( \ell \)-stable block decomposition. This has two blocks, each of size \( m \). Its stabiliser contains \( H \) and also contains elements swapping the two blocks, so has order \( 2\sharp H \). Thus

\[
p(2, m) = \frac{2\sharp H}{(2m)!} = \left(\frac{2m - 1}{m}\right)^{-1}.
\]

In particular, taking \( m = 2 \), we get \( p(2, 2) = 1/3 \). Thus, when the doubling map \( f(x) = 2x \mod 1 \) is composed with permutations \( \sigma \) of the 4 equal subintervals of \([0, 1)\), those \( \sigma \in S_4 \) for which \( f \circ \sigma \) is not mixing form a single coset of a subgroup of index 3 in \( S_4 \). (Any such subgroup is dihedral of order 8.)

### 5.3 \( \ell = 3 \)

There are 4 nontrivial \( \ell \)-stable block decompositions:

(1) \( \{1, 2\}, \{3\} \);

(2) \( \{1, 3\}, \{2\} \);

(3) \( \{2, 3\}, \{1\} \);

(4) \( \{1\}, \{2\}, \{3\} \).

We shall apply the Inclusion-Exclusion Principle directly.

The stabiliser of any one of the block decompositions (i), (ii), (iii) has order \((2m)!m! = \binom{2m}{m}\sharp H \) since it contains any permutation of the \( 2m \) elements in the block consisting of 2 cosets. The stabiliser of the block decomposition (iv) has order \( 6\sharp H \) since we may permute the 3 blocks amongst themselves in \( 3! = 6 \) ways.

We now consider the stabilisers of any of the \( \binom{3}{2} = 6 \) pairs of the block decompositions. First consider the 3 pairs consisting of any two of (i), (ii) or (iii).
Any permutation fixing such a pair must fix each coset, so the stabiliser of any of these 3 pairs is just $H$. A permutation stabilising (say) (i) and (iv) could also swap the cosets $C_1$ and $C_2$, so the stabilisers of the other 3 pairs have orders $2\sharp H$. The stabiliser of any 3 (or all 4) block decompositions is again just $H$. Thus the precise number of permutations in $S_{3m}$ fixing at least one of the block decompositions is

$$\left(3\binom{2m}{m} + 6 - 3 - 3 \times 2 + \binom{4}{3} - 1\right)\sharp H = 3\binom{2m}{m}\sharp H = 3(2m)!m!.$$

Hence

$$p(3, m) = \frac{1}{(3m)!} \times 3(2m)!m! = \left(\frac{3m - 1}{2m}\right)^{-1}.$$

In particular, $p(3, 2) = 1/5.

5.4 \quad \ell = 4$

For the sake of brevity, we only sketch the argument in this case. There are 14 nontrivial $\ell$-stable block decompositions, but we can eliminate half of them before applying the Inclusion-Exclusion Principle. The stabiliser of the unique block decomposition with block sizes 1, 1, 1, 1 contains $H$ as a normal subgroup, the quotient being the group $S_4$ of all permutations of the 4 cosets. Let $\pi \in S_4$ be the image of some $\sigma$ in the stabiliser. Then either $\pi$ or $\pi^2$ has more than one orbit on $\{1, 2, 3, 4\}$, and we can use this to find another block decomposition stabilised by $\sigma$. Also, any permutation in the stabiliser of a block decomposition with block sizes 2, 1, 1, say $\{1, 2\}, \{3\}, \{4\}$, also stabilises the block decomposition $\{1, 2\}, \{3, 4\}$. This means we only need to consider the stabilisers of the 4 block decompositions with block sizes 3, 1 and the 3 block decompositions with block sizes 2, 2.

We can then apply to the Inclusion-Exclusion Principle to the stabilisers of these 7 block decompositions, by considering all possible pairs, and, for each pair, considering any ways of extending the pair to a larger subset of the blocks with stabiliser larger than $H$. In doing so, we take care not to include any higher order stabilisers which have already been counted. (This means that the order in which we consider the pairs is important.) We omit the details of this calculation. After some simplification, we obtain the formula

$$p(4, m) = \left[4\left(\binom{3m}{m,m,m,m} + 6\binom{2m}{m}^2 - 12\binom{2m}{m}\right)\right] \frac{(m!)^4}{(4m)!}.$$

In particular, we find

$$p(4, 2) = \frac{1}{5}, \quad p(4, 3) = \frac{37}{1540}.$$

Note that, in contrast to the cases $\ell = 2$ and $\ell = 3$, $p(4, m)$ is not in general the reciprocal of an integer.
5.5 Arbitrary $\ell$

For larger values of $\ell$, obtaining an explicit formula for $p(\ell, m)$ by the Inclusion-Exclusion Principle becomes impractical, but we can at least determine the asymptotic behaviour of the dominant term for large $m$ when $\ell$ is fixed. As this does not contribute to our goal of investigating the effect of composing multiplication by a fixed $m$ with permutations, we will content ourselves with a brief sketch of the argument.

Fix $\ell \geq 2$. Arguing as above, we find from the Inclusion-Exclusion Principle that $p(\ell, m)$ is a sum of terms of the form

$$C(r_1 m)! \cdots (r_j m)! \over (\ell m)! = C \left( \frac{\ell m}{r_1 m, \ldots, r_j m} \right)^{-1},$$

(25)

where $r_1 + \cdots + r_j = \ell$ with $j \geq 2$ and $1 \leq r_1 \leq \ldots \leq r_j$, and where $C$ is a (positive or negative) integer depending on $\ell$ and the $r_i$. One such term (corresponding to $\ell$-stable block decompositions with 2 blocks of sizes $(\ell - 1)m$ and $m$) has $r_1 = 1$, $r_2 = \ell - 1$ and $C = \ell$. For $\ell \geq 3$, there are $\ell$ such block decompositions each with stabiliser of order $((\ell - 1)m)!m!$, while for $\ell = 2$ there is only one block decomposition but its stabiliser has order $2(m!)^2$. Thus we have $C = \ell$ in both cases.

Applying Stirling’s formula

$$n! \sim \sqrt{2\pi n} \left( \frac{n}{e} \right)^n$$

as $n \to \infty$, (see for example [19, p. 47]) to each factorial in (25) separately, we find that the term (25) is asymptotic to

$$D m^{(j-1)/2} \rho^m$$

as $m \to \infty$, where

$$D = C(2\pi)^{(j-1)/2} \sqrt{\frac{r_1 \cdots r_j}{\ell}}$$

and

$$\rho = \prod_{i=1}^{j} \left( \frac{r_i}{\ell} \right)^{r_i}.$$ 

Note that $0 < \rho < 1$. Moreover, one can verify that $\rho$ is maximal for the term with $j = 2$, $r_1 = 1$, $r_2 = \ell - 1$. (First show that splitting some $r_i$ as $r_i = r' + r''$ with $r'$, $r'' \geq 1$ decreases $\rho$, so that the maximum must occur when $j = 2$. Then show that, amongst terms with $j = 2$, $\rho$ is maximum at $r_1 = 1$ by differentiating the logarithm of $x^r (\ell - x)^{\ell - x}$.) This term therefore dominates the asymptotic behaviour of $p(\ell, m)$ as $m \to \infty$.

This gives us the following result:

**Lemma 5.6** For fixed $\ell \geq 2$, we have

$$p(\ell, m) \sim \sqrt{2\pi(\ell - 1)\ell m} \left( \frac{\ell - 1}{\ell^2} \right)^m$$

as $m \to \infty$. 

17
6 Asymptotic behaviour as $\ell \to \infty$

Our goal in this section is to use combinatorial arguments to complete the proof of Theorem 3.

From Theorem 2 we have

$$p(\ell, m) \leq \frac{1}{(ml)!} \sum \mathbb{Z}G_B,$$

where the sum is over all nontrivial $\ell$-stable block decompositions $B$. Given integers $1 \leq r_1 \leq \ldots \leq r_j$ with $r_1 + \cdots + r_j = \ell$, we consider the contribution to (26) from all block decompositions $B$ with block sizes $mr_1, \ldots, mr_j$. The number of such block decompositions can be given in terms of a multinomial coefficient. Let us set

$$n_i(r_1, \ldots, r_j) = \# \{ h : r_h = i \}$$

and

$$d(r_1, \ldots, r_j) = \prod_{i=1}^{\ell} n_i(r_1, \ldots, r_j).$$

Then the number of $\ell$-stable block decompositions $B$ of $\{1, \ldots, ml\}$ with block sizes $mr_1, \ldots, mr_j$ is

$$\frac{1}{d(r_1, \ldots, r_j)} \left( \begin{array}{c} \ell \\ r_1, \ldots, r_j \end{array} \right).$$

Moreover, any such $B$ is preserved by a group of permutations $S_{mr_1} \times \cdots \times S_{mr_j}$ permuting the elements within each block, but we can also permute the blocks of any given size amongst themselves. Thus we have

$$\mathbb{Z}G_B = d(r_1, \ldots, r_j) \left( \prod_{h=1}^{j} (mr_h)! \right).$$

The contribution to (26) from block decompositions with block sizes $mr_1, \ldots, mr_j$ is therefore

$$\frac{1}{(ml)!} \left[ d(r_1, \ldots, r_j) \left( \prod_{h=1}^{j} (mr_h)! \right) \right] \left[ \frac{1}{d(r_1, \ldots, r_j)} \left( \begin{array}{c} \ell \\ r_1, \ldots, r_j \end{array} \right) \right]^{-1},$$

which simplifies to

$$\left( \begin{array}{c} \ell \\ r_1, \ldots, r_j \end{array} \right) \left( \begin{array}{c} ml \\ mr_1, \ldots, mr_j \end{array} \right)^{-1}. $$

Thus we may rewrite (26) as

$$p(\ell, m) \leq \sum_{j=2}^{\ell} b_j(\ell),$$

where

$$b_j(\ell) = \sum_{1 \leq r_1 \leq \ldots \leq r_j, \ r_1 + \cdots + r_j = \ell} \left( \begin{array}{c} \ell \\ r_1, \ldots, r_j \end{array} \right) \left( \begin{array}{c} ml \\ mr_1, \ldots, mr_j \end{array} \right)^{-1}.$$

The definition of $b_j(\ell)$ makes sense for $j = 1$, giving $b_1(\ell) = 1$.  

18
Proposition 6.1 For $2 \leq j \leq \ell$, we have

$$b_j(\ell) \leq \sum_{r=1}^{\lfloor \ell/j \rfloor} \sum_{1 \leq r_1, \ldots, r_j \leq \ell-r_1} \left( \frac{\ell}{r_1, \ldots, r_j} \right) \left( \frac{m\ell}{mr_1, \ldots, mr_j} \right).$$

Proof. Separating out $r_1$ in the definition of $b_j(\ell)$, we may write

$$b_j(\ell) \leq \sum_{r_1=1}^{\lfloor \ell/j \rfloor} \sum_{1 \leq r_2, \ldots, r_j \leq \ell-r_1} \left( \frac{\ell}{r_1, \ldots, r_j} \right) \left( \frac{m\ell}{mr_1, \ldots, mr_j} \right).$$

(Note that we have “$\leq$” rather than “$=$” since the condition $r_2 \geq r_1$ has been weakened to $r_2 \geq 1$.) The result then follows on using the (easily verified) identity

$$\left( \frac{\ell}{r_1, \ldots, r_j} \right) = \left( \frac{\ell}{r_1} \right) \left( \frac{\ell-r_1}{r_2, \ldots, r_j} \right),$$

together with the corresponding identity where all the arguments are multiplied by $m$. 

Lemma 6.2 Suppose that $m \geq 2$ and $\ell \geq 3$. Then, for $1 \leq j \leq \ell$, we have

$$b_j \leq \left( \frac{2e}{\ell} \right)^{(m-1)(j-1)}. \quad (28)$$

Proof. We argue by induction on $j$. The result holds for $j = 1$ since $b_1(\ell) = 1$. Suppose that $2 \leq j \leq \ell$ and the result holds for $j - 1$. From Proposition 6.1, we have

$$b_j(\ell) \leq \left( \frac{\ell}{1} \right) \left( \frac{m\ell}{m} \right)^{-1} b_{j-1}(\ell - 1) + \sum_{r=2}^{\lfloor \ell/j \rfloor} \left( \frac{\ell}{r} \right) \left( \frac{m\ell}{mr} \right)^{-1} b_{j-1}(\ell - r). \quad (29)$$

For the first term, we have the estimate

$$\left( \frac{\ell}{1} \right) \left( \frac{m\ell}{m} \right)^{-1} b_{j-1}(\ell - 1) \leq \frac{\ell (m!)}{(m\ell)(m\ell - 1) \ldots (m\ell - \ell + 1)} \left( \frac{2e}{\ell} \right)^{(m-1)(j-2)} \leq \frac{(m-1)!}{m^{m-1}(\ell - 1)^{m-1}} \left( \frac{2e}{\ell} \cdot \frac{\ell}{\ell - 1} \right)^{(m-1)(j-2)} = \frac{1}{2} \left( \frac{1}{2} \cdot \frac{\ell}{\ell - 1} \cdot 2 \right)^{m-1} \left( \frac{2e}{\ell} \cdot \frac{\ell}{\ell - 1} \right)^{(m-1)(j-2)} \leq \frac{1}{2m e^{m-1}} \left( \frac{2e}{\ell} \right)^{(m-1)(j-2)} \left( \frac{\ell}{\ell - 1} \right)^{(m-1)(j-1)}.$$}

But

$$\left( \frac{\ell}{\ell - 1} \right)^{(m-1)(j-1)} \leq \left( \frac{\ell}{\ell - 1} \right)^{(m-1)(\ell-1)} < e^{m-1}$$
since \((1 + \frac{1}{n})^{n}\) is an increasing function of \(n\) and \((1 + \frac{1}{n})^{n} \to e\) as \(n \to \infty\). As \(m \geq 2\), it follows that
\[
\binom{\ell}{1} \left( \frac{m\ell}{m} \right)^{-1} b_{j-1}(\ell - 1) \leq \frac{1}{4} \left( \frac{2e}{\ell} \right)^{(m-1)(j-1)}.
\] (30)

We now consider each term in the sum in (29). For \(2 \leq r \leq \lfloor \ell/j \rfloor\), we have
\[
\binom{\ell}{r} \leq \binom{m\ell}{mr}.
\]
(This is obvious combinatorially: some of the ways of choosing \(mr\) objects from \(m\ell\) are given by choosing \(r\) objects from the first \(\ell\), then another \(r\) from the second \(\ell\), and so on.) Also, since \(2 \leq r \leq \ell/2\), we have
\[
\binom{\ell}{2} \leq \binom{\ell}{r}.
\]
Thus
\[
\binom{\ell}{r} \left( \frac{m\ell}{mr} \right)^{-1} \leq \binom{\ell}{r}^{1-m} \leq \binom{\ell}{2}^{1-m} = \frac{2^{m-1}}{\ell^{m-1}(\ell - 1)^{m-1}}.
\]
From the induction hypothesis, we have
\[
b_{j-1}(\ell - r) \leq \left( \frac{2e}{\ell} \right)^{(m-1)(j-2)} \leq \left( \frac{2e}{\ell} \right)^{(m-1)(j-2)} \left( \frac{j}{j-1} \right)^{(m-1)(j-2)},
\]
and \((j/(j - 1))^{j-2} < (j/(j - 1))^{j-1} < e\). Thus
\[
\sum_{r=2}^{\lfloor \ell/j \rfloor} \binom{\ell}{r} \left( \frac{m\ell}{mr} \right)^{-1} b_{j-1}(\ell - r) < \frac{\ell}{j} \frac{2^{m-1}}{\ell^{m-1}(\ell - 1)^{m-1}} \left( \frac{2e}{\ell} \right)^{(m-1)(j-2)} e^{m-1}
\]
\[
= \frac{\ell}{j(\ell - 1)^{m-1}} \left( \frac{2e}{\ell} \right)^{(m-1)(j-1)}.
\]
But as \(j \geq 2\), \(m \geq 2\) and \(\ell \geq 3\), we have
\[
\frac{\ell}{j(\ell - 1)^{m-1}} \leq \frac{\ell}{2(\ell - 1)} \leq \frac{3}{4}.
\]
Substituting the last estimate and (30) into (29), we therefore obtain
\[
b_{j} \leq \left( \frac{2e}{\ell} \right)^{(m-1)(j-1)},
\]
which completes the induction. \(\blacksquare\)
Proof of Theorem 3. Since we are assuming $\ell \geq 6$, we have $2e/\ell < 1$. It then follows from (27) and Lemma 6.2 that

$$p(\ell, m) < \sum_{j=2}^{\infty} \left( \frac{2e}{\ell} \right)^{(m-1)(j-1)}$$

$$= \left( \frac{2e}{\ell} \right)^{m-1} \left[ 1 - \left( \frac{2e}{\ell} \right)^{m-1} \right]^{-1}.$$  

As $m \geq 2$ and $2e/\ell < \frac{11}{10}$, this gives

$$p(\ell, m) < \left[ 1 - \left( \frac{2e}{\ell} \right)^{m-1} \right] \left( \frac{2e}{\ell} \right)^{m-1} < 11 \left( \frac{2e}{\ell} \right)^{(m-1)},$$  

as required.  

7 Mixing for subshifts

In this section, we give an example to show that the analogue of Theorem 3 no longer holds if we replace the multiplication-by-$m$ map $f$ with another Markov map on the unit interval. We consider the piecewise continuous function $f : [0, 1) \rightarrow [0, 1)$ given by

$$f(x) = \begin{cases} 
2x & \text{if } 0 \leq x < \frac{1}{2}, \\
x - \frac{1}{2} & \text{if } \frac{1}{2} \leq x < 1. 
\end{cases}$$  

(31)

Fix $\ell \geq 1$ and divide $[0, 1)$ into $N = 2\ell$ equal subintervals

$$I_j = \left[ \frac{j}{2\ell}, \frac{j+1}{2\ell} \right), \quad 0 \leq j \leq 2\ell - 1.$$  

For a permutation $\sigma \in S_{2\ell}$ of these subintervals, let $g = \sigma \circ f$. We have the following result.

**Theorem 6** The proportion of permutations $\sigma$ for which $g$ is non-mixing (and indeed, non-ergodic) is bounded away from 0 as $\ell \rightarrow \infty$.

**Proof.** For any subset $A \subseteq \{0, \ldots, 2\ell - 1\}$, define $\tilde{g}(A) \subseteq \{0, \ldots, 2\ell - 1\}$ by

$$\tilde{g}(A) = \{ \sigma(2j), \sigma(2j+1) : j \in A, j < \ell \} \cup \{ \sigma(j+\ell) : j \in A, j \geq \ell \}.$$  

Then, analogously to Proposition 4.2, we have

$$g \left( \bigcup_{a \in A} I_a \right) = \bigcup_{b \in \tilde{g}(A)} I_b.$$ 

21
Note however that Proposition 4.3 no longer holds: for example, if \( A = \{0, \ell, \ell + 1\} \) (with \( \ell \geq 2 \)) then \( \tilde{g}(A) = \{0, 1\} \) has fewer elements than \( A \).

Now if there is some nonempty subset \( A \) such that \( \tilde{g}^r(A) \neq \{0, \ldots, 2\ell - 1\} \) for all \( r \geq 0 \) (respectively, such that \( \bigcup_{r \geq 0} \tilde{g}^r(A) \neq \{0, \ldots, 2\ell - 1\} \)) then \( g \) is non-mixing (respectively, non-ergodic). But if \( \sigma \) has the property that \( \sigma(j - \ell) = j \) for some \( j \geq \ell \) then, taking \( A = \{j\} \), we have \( \tilde{g}^r(A) = A \) for all \( r \). Thus \( g \) is both non-mixing and non-ergodic. We therefore need to investigate the proportion of permutations with the above property.

Let \( 1 \leq m \leq \ell \) and let \( S \) be a subset of \( \{\ell, \ldots, 2\ell - 1\} \) of size \( m \). There are \((2\ell - m)! \) permutations \( \sigma \in S_{2\ell} \) such that \( \sigma(j - \ell) = j \) for all \( j \in S \). Moreover, the number of such sets \( S \) of size \( m \) is \( \binom{\ell}{m} \). Thus, by the Inclusion-Exclusion Principle, the proportion of permutations \( \sigma \in S_{2\ell} \) with \( \sigma(j - \ell) = j \) for at least one \( j \geq \ell \) is

\[
\sum_{m=1}^{\ell} (-1)^{m-1} a_m
\]

where

\[
a_m = \binom{\ell}{m} \frac{(2\ell - m)!}{(2\ell)!}.
\]

Now the terms in the alternating series are decreasing: for \( 1 \leq m < \ell \) we have

\[
\frac{a_{m+1}}{a_m} = \frac{m!(\ell - m)!(2\ell - m - 1)!}{(m+1)!(\ell - m - 1)!(2\ell - m)!} = \frac{\ell - m}{(m+1)(2\ell - m)} < \frac{1}{2(m+1)}.
\]

Hence the required proportion is bounded below by

\[
a_1 - a_2 = \frac{1}{2} - \frac{\ell(\ell - 1)}{2(2\ell)(2\ell - 1)} > \frac{3}{8}.
\]

So we have proved that, for each \( \ell \geq 1 \), the function \( \sigma \circ f \) is non-mixing (indeed, non-ergodic) for more than \( 3/8 \) of the permutations \( \sigma \in S_{2\ell} \). Although the map \( f \) in (31) is not uniformly expanding, a finite power of \( f \) is. Thus we can still apply the results of Section 3 to study the mixing rates. The associated Fredholm and transition matrices are given (respectively.) by:

\[
\Phi(z) = \begin{pmatrix} z/2 & z/2 \\ z & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix},
\]

and thus the invariant density is given by \( \rho(x) = \frac{4}{3} \mathcal{X}_1(x) + \frac{2}{3} \mathcal{X}_2(x) \), (see (14)). Using this information we get the following results.

1. \( r_{ess} = e^{-\xi} \) where \( \xi = \int_0^1 (\log f'(x))\rho(x)dx = \frac{2}{3} \log 2 \).
2. The topological entropy is given by \( \log(1 + \sqrt{5}) < r_{ess} \).
3. \( \det(I - \Phi(z)) = 0 \) implies that \( z = 1, -2 \). Thus 1 is the only eigenvalue of \( \mathcal{L}_f \) outside \(|z| > r_{ess}\).
It remains an open problem to determine the corresponding quantities for \( \sigma \circ f \) with \( \sigma \in S_N, N \geq 1 \). To investigate the rate of mixing of \( \sigma \circ f \) (relative to \( f \) alone), we would also need to calculate the invariant density associated to each \( \sigma \in S_N \) (since Lebesgue measure is not invariant). This would allow us to compute the corresponding value of \( r_{\text{ess}} := r_{\text{ess}}(\sigma) \). The isolated eigenvalues of \( L_{\sigma \circ g} \) would be found via the associated Fredholm matrices.

8 Proof of Theorem 4

In this Section we consider \( f(x) = mx \mod 1 \) and \( \sigma \in S_N \). We will exhibit permutation transformations for which \( \sigma \circ f \) mixes arbitrarily slowly in the sense of (19). The proof requires a detailed study of the eigenvalues of the Fredholm matrices \( \Phi(z) \) associated to \( \sigma \circ f \). These matrices are attached to a partition of \([0, 1]\) on which \( \sigma \circ f \) is Markov, so we first need to determine such a partition.

For \( k \geq 1 \), consider the partition
\[
P_k := \{(j-1)/k, j/k) : 1 \leq j \leq k\}
\]
of \([0, 1)\) into \( k \) equal subintervals. Then the map \( f \) is Markov w.r.t. \( P_m \), while the map \( \sigma \) is Markov w.r.t. \( P_N \). The map \( \sigma \circ f \), however, is in general not Markov w.r.t. either of these partitions. For example consider \( m = 2, N = 3 \). Clearly any \( \sigma \in S_3 \) is Markov on the partition
\[
P_3 = \{[0, 1/3), [1/3, 2/3), [2/3, 1]\}.
\]
However, if we take the permutation \( \sigma \) interchanging the last two subintervals, then we have
\[
\sigma \circ f(x) = \begin{cases} 
2x & \text{if } 0 \leq x < 1/6, \\
2x + 1/3 & \text{if } 1/6 \leq x < 1/3,
\end{cases}
\]
so that \( \sigma \circ f \) is not continuous on \([0, 1/3)\) and hence not Markov on \( P \). In general, to ensure that \( \sigma \circ f \) is Markov for all \( \sigma \in S_N \), we must work with the partition \( P_{Nm} \).

Due to our specific choice \( f(x) = mx \mod 1 \), the \( Nm \times Nm \) matrix \( \Phi(1) \) is precisely the probability-transition matrix between the Markov states, and has all its entries in \( \{0, 1/m\} \). If \( \lambda \in \text{Spec}(L_f|_{BV}) \) then we know that \( z = 1/\lambda \) is a solution to \( D(z) = \det(I - \Phi(z)) = 0 \). It is therefore an equivalent problem to consider the corresponding equation (in \( \lambda \)) to \( \det(B - \lambda I) = 0 \), where \( B \) is the state transition matrix (with entries in \( \{0, 1\} \)). Hence if \( \lambda \) is an eigenvalue of \( B \), then \( \lambda = \lambda \in \text{Spec}(L_f|_{BV}) \).

Note that in our case, \( m\Phi(1) \) is precisely the state transition matrix \( B \). We will show that the eigenvalues of \( \Phi(1) \) can in fact be determined from the \( N \times N \) transition matrix associated with the partition \( P_N \) (on which \( \sigma \circ f \) need not be Markov).

We must first define some notation. Following the conventions of Section 2 we index the subintervals in \( P_k \) by \( \{0, 1, \ldots, k-1\} \). We therefore begin the numbering of the rows and columns in the associated matrices from 0. We define \( A(m, N) \) and \( B(m, N) \) to be the state transition matrices for \( f \) w.r.t. \( P_N \) and \( P_{Nm} \) respectively.
Thus for $0 \leq i, j \leq N - 1$ we have

$$A(m, N)_{ij} = \begin{cases} 1 & \text{if } j \equiv mi + d \mod N \text{ with } 0 \leq d \leq m - 1, \\ 0 & \text{otherwise}, \end{cases}$$

and for $0 \leq i, j \leq Nm - 1$ we have

$$B(m, N)_{ij} = \begin{cases} 1 & \text{if } j \equiv mi + d \mod Nm \text{ with } 0 \leq d \leq m - 1, \\ 0 & \text{otherwise}. \end{cases}$$

For example, when $m = 2$ and $N = 3$, we have

$$A(2, 3) = \begin{pmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{pmatrix}, \quad B(2, 3) = \begin{pmatrix} 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix}.$$

The eigenvalues for $A(2, 3)$ are $\{\pm 1, 2\}$, while those for $B(2, 3)$ are $\{\pm 1, 2, 0\}$, where the eigenspace for the eigenvalue 0 has dimension 3. In the case $m = 3, N = 5$ we have:

$$A(3, 5) = \begin{pmatrix} 1 & 1 & 1 & 0 & 0 \\ 1 & 0 & 0 & 1 & 1 \\ 0 & 1 & 1 & 1 & 0 \\ 1 & 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 1 & 1 \end{pmatrix},$$

and the eigenvalues for $A(3, 5)$ are $\{3, \pm i, \pm 1\}$. Note that all row sums and columns sums in both $A(m, N)$ and $B(m, N)$ are $m$. Each row in either matrix consists of $m$ consecutive occurrences of 1 (where, in the case of $A(m, N)$ these may “wrap around” from the last column to the first). The rows of $B(m, N)$ naturally fall into $m$ identical blocks each consisting of $N$ rows, and the columns into $N$ blocks each consisting of $m$ identical columns, as indicated for $B(2, 3)$ above.

The corresponding state transition matrices for $\sigma \circ f$ are obtained by permuting the columns of $A(m, N)$ and $B(m, N)$. More precisely, given a permutation $\sigma$ of $\{0, \ldots, N - 1\}$, let $P(\sigma)$ be the $N \times N$ permutation matrix given by

$$P(\sigma)_{ij} = \begin{cases} 1 & \text{if } j = \sigma(i), \\ 0 & \text{otherwise}, \end{cases}$$

and let $Q(\sigma)$ be the $Nm \times Nm$ matrix obtained by replacing each entry 1 (respectively, 0) in $P(\sigma)$ by an $m \times m$ identity matrix (respectively, zero matrix). Then the state transition matrices for $\sigma \circ f$ w.r.t. the partitions $P_N$ and $P_{Nm}$ are $A(m, N)P(\sigma)$ and $B(m, N)Q(\sigma)$ respectively. For example, if $m = 2, N = 3$ and $\sigma$ is the 3-cycle $(0, 1, 2)$
then
\[ P(\sigma) = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix}, \quad Q(\sigma) = \begin{pmatrix} 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \end{pmatrix}, \]

so that
\[ A(2, 3)P(\sigma) = \begin{pmatrix} 0 & 1 & 1 \\ 1 & 1 & 0 \\ 1 & 0 & 1 \end{pmatrix}, \quad B(2, 3)Q(\sigma) = \begin{pmatrix} 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 \\ 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 \\ 1 & 1 & 0 & 0 & 0 & 0 \end{pmatrix}. \]

Note also that \( P(\sigma)A(m, N) \) is the matrix obtained by applying the inverse permutation \( \sigma^{-1} \) to the rows of \( A(m, N) \).

To determine the mixing rate of \( \sigma \circ f \), we need to investigate the eigenvalues of the Fredholm matrix \( \Phi(1) = m^{-1}B(m, N)Q(\sigma) \) corresponding to the partition \( \mathcal{P}_{Nm} \) on which \( \sigma \circ f \) is Markov. Clearly \( \lambda \) is an eigenvalue of \( \Phi(1) \) if and only if \( m\lambda \) is an eigenvalue of \( B(m, N)Q(\sigma) \), so it suffices to find the eigenvalues of the latter \( Nm \times Nm \) matrix. In fact we only need consider \( N \times N \) matrices.

**Lemma 8.1** For all \( m, N \) and all \( \sigma \in S_N \), the nonzero eigenvalues of \( B(m, N)Q(\sigma) \) are the same as those of \( A(m, N)P(\sigma) \).

**Proof.** For brevity, we write \( A = A(m, N) \), \( B = B(m, N) \), \( P = P(\sigma) \) and \( Q = Q(\sigma) \).

We view \( BQ \) as determining a linear endomorphism \( \theta \) on the space \( V = \mathbb{C}^{Nm} \) of column vectors. Clearly \( BQ \) has rank \( N \), since the first \( N \) rows are linearly independent and the remaining rows merely repeat these. The kernel \( W \) of \( \theta \) therefore has dimension \( N(m - 1) \), and \( \theta \) induces an endomorphism \( \overline{\theta} \) on the quotient space \( V/W \) of dimension \( N \). The eigenvalues of \( \theta \) (that is, of \( BQ \)) are therefore the eigenvalues of \( \overline{\theta} \), together with the eigenvalue 0 of multiplicity \( N(m - 1) \) coming from \( W \). The result will therefore follow if we show that the matrix \( AP \) represents \( \overline{\theta} \).

We define vectors \( \mathbf{v}^{r,s} \) for \( 0 \leq r \leq N - 1 \), \( 0 \leq s \leq m - 1 \) (independent of \( \sigma \)) as follows. For \( s = 0 \), set
\[
\mathbf{v}^{r,0}_i = \begin{cases} 
1 & \text{if } i = mr, \\
0 & \text{otherwise},
\end{cases}
\]
and for \( s > 0 \),
\[
\mathbf{v}^{r,s}_i = \begin{cases} 
-1 & \text{if } i = mr, \\
1 & \text{if } i = mr + s, \\
0 & \text{otherwise}.
\end{cases}
\]
For example, if \( m = 2 \) and \( N = 3 \) we have

\[
\begin{align*}
v^{0,0} &= \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix}, & v^{0,1} &= \begin{pmatrix} -1 \\ 0 \\ 0 \\ 0 \end{pmatrix}, & v^{1,0} &= \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \end{pmatrix}, & v^{1,1} &= \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix}, & v^{2,0} &= \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}, & v^{2,1} &= \begin{pmatrix} 0 \\ 0 \\ 0 \\ -1 \end{pmatrix},
\end{align*}
\]

where the horizontal lines correspond to the division of the columns of \( B(2,3)Q(\sigma) \) into blocks.

It is clear that the \( v^{r,s} \) form a basis for \( V \), and that if \( s \neq 0 \) then \( BQ v^{r,s} = 0 \). Hence the \( N(m-1) \) vectors \( v^{r,s} \) for \( s \neq 0 \) form a basis for \( W \). Thus the \( N \) cosets \( v^{r,0} + W \) form a basis for \( V/W \). If we partition \( BQ \) into \( m \times m \) blocks (as in the above example), the matrix of \( \theta \) with respect to this basis is then obtained by replacing each block with the sum of one of its (identical) columns. This gives precisely the matrix \( AP \).

We next consider a matrix related to \( A(m,N) \) but with eigenvalues that are easy to determine. Let \( C(m,N) \) be the \( N \times N \) circulant matrix with entries

\[
C(m,N)_{ij} = \begin{cases} 1 & \text{if } j \equiv i + r \mod N \text{ with } 0 \leq r \leq m - 1, \\ 0 & \text{otherwise} \end{cases}
\]

for \( 0 \leq i, j \leq N - 1 \). For example,

\[
C(2,5) = \begin{pmatrix} 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 1 \\ 1 & 0 & 0 & 0 & 1 \end{pmatrix}.
\]

**Proposition 8.2** The matrix \( C(m,N) \) has eigenvalues

\[
\lambda_j = \sum_{t=0}^{m-1} \omega_j^t, \quad 0 \leq j \leq N - 1,
\]

where \( \omega_j = e^{2\pi ij/N} \). In particular, \( \lambda_0 = m \) and, for \( 1 \leq j \leq N - 1 \),

\[
|\lambda_j| = \left| \frac{\sin(mj\pi/N)}{\sin(j\pi/N)} \right|.
\]

Moreover,

\[
\det(C(m,N)) = \begin{cases} 0 & \text{if } \gcd(m,N) > 1; \\ \pm m & \text{if } \gcd(m,N) = 1. \end{cases}
\]

**Proof.** We set \( C = C(m,N) \). It is easily checked that

\[
v_j = (1, \omega_j, \omega_j^2, \ldots, \omega_j^{N-1})^T
\]
is an eigenvector of $C$ with eigenvalue $\lambda_j$. Although the $\lambda_j$ are not necessarily distinct, the $N$ vectors $v_j$ are linearly independent since

$$\det(\omega^k_{j,k})_{0 \leq j,k < N} = \prod_{j < k}(\omega_k - \omega_j) \neq 0,$$

so there are no further eigenvalues. Trivially $\lambda_0 = m$. For $j \neq 0$, we have

$$\lambda_j = \frac{e^{2\pi i mj/N} - 1}{e^{2\pi i j/N} - 1}.$$

Taking the modulus gives the required expression in equation (33).

Moreover, we have

$$|\det(C)| = \prod_{j=0}^{N-1} |\lambda_j| = m \prod_{j=1}^{N-1} \left| \frac{\sin(mj\pi/N)}{\sin(j\pi/N)} \right|.$$

If $\gcd(m, N) = s > 1$ then, taking $j = N/s$, we have $\sin(mj\pi/N) = 0$ and hence $\det(C) = 0$.

If $\gcd(m, N) = 1$ then the residues $mj \mod N$ are just the residues $j \mod N$ in some order, so the product reduces to 1.

The maximum $|\lambda_j|$ for $1 \leq j \leq N - 1$ in Proposition 8.2 is attained at $j = 1$. Although this is essentially elementary, it is trickier to verify than it might appear, so we include a proof.

**Proposition 8.3**

$$\max_{1 \leq j \leq N-1} \left| \frac{\sin(mj\pi/N)}{\sin(j\pi/N)} \right| = \left| \frac{\sin(m\pi/N)}{\sin(\pi/N)} \right|.$$

**Proof.** Since $|\sin(\pi k \pm x)| = |\sin x|$ for all $k \in \mathbb{Z}$, we may assume that $1 \leq m \leq N/2$, and moreover it suffices to take $1 \leq j \leq N/2$. We consider the two functions $u(x) = \sin mx / \sin x$ and $v(x) = 1 / \sin x$ on the interval $(0, \pi)$. Now $u(x)$ has precisely $m - 1$ zeros on this interval, at $x = h\pi/m$ for $1 \leq h \leq m - 1$. Since $u(x)$ may be written on as a polynomial of degree $m - 1$ in $\cos x$, and $\cos x$ is monotonically decreasing on this interval, it follows that $u(x)$ has precisely $m - 2$ stationary points, one in each of the intervals $(h\pi/m, (h + 1)\pi/m)$ for $1 \leq h \leq m - 2$. In particular, as $\lim_{x \to 0} u(x) = m$, it follows that $u(x)$ is positive and decreasing on $(0, \pi/m)$, so that $u(\pi/N) > u(j\pi/N) \geq 0$ if $2 \leq j \leq N/m$. On the other hand, as $v(x)$ is positive and decreasing throughout $(0, \pi/2)$, we have for $N/m \leq j \leq N/2$ that $|u(j\pi/N)| \leq v(j\pi/N) \leq v(\pi/m) < v(\pi/2m)$. But $v(\pi/2m) = u(\pi/2m) \leq u(\pi/N)$ as $m \leq N/2$. Hence $|u(j\pi/N)| < u(\pi/N)$ for $2 \leq j \leq N/2$, as required.

We now seek to relate the eigenvalues of the matrices $A(m, N)P(\sigma)$ to those of $C(m, N)$. After a suitable scaling, these matrices are doubly stochastic. Our next result gives some information on the behaviour of the eigenvalues of a column stochastic
Lemma 8.4 Let the subspace $V$ orthogonal, so that $|z|$ where $B$ basis of eigenvectors for $x$ index such that $N \times B$ necessarily an eigenvector for $\lambda$ as in the proof of Proposition 8.2. Then the normalised so that $||\eta|| C$ column, doubly stochastic. For $A(m, N)$ as above, the probability transition matrices $m^{-1}A(m, N)$ are doubly stochastic. Any permutation matrix $P(\sigma)$ is doubly stochastic and orthogonal.

We view our matrices as linear maps on the space $\mathbb{C}^N$ of column vectors, endowed with the usual complex inner product $(x, y) = \sum_{j=1}^{N} x_j \bar{y}_j$ for $x = (x_1, \ldots, x_N)^T$, $y = (y_1, \ldots, y_N)^T$, and write $||x|| = \sqrt{(x, x)}$ for $x \in \mathbb{C}^N$. Any row stochastic matrix has the obvious eigenvector $e = (1, \ldots, 1)^T$ with eigenvalue 1. It is well-known that any eigenvalue $\lambda$ satisfies $|\lambda| \leq 1$. If $B$ is a column stochastic matrix then $e$ is not necessarily an eigenvector for $B$, but if $(x, e) = 0$ then $(Bx, e) = 0$, so that $B$ preserves the subspace $V_0$ of vectors in $\mathbb{C}^N$ perpendicular to $e$.

Lemma 8.4 Let $B$ be an $N \times N$ column stochastic matrix. Then the eigenvalues of $B^T B$ on $V_0$ are real and nonnegative. Let $\eta$ be the largest of these, and let $P$ be an $N \times N$ orthogonal, column stochastic matrix (e.g. a permutation matrix). Then every eigenvalue $\lambda$ of $BP$ on $V_0$ satisfies

$$|\lambda| \leq \sqrt{\eta}.$$

Moreover, if $B$ is a circulant matrix then

$$\sqrt{\eta} = \max\{|\lambda| : \lambda \text{ is an eigenvalue of } B \text{ on } V_0\}.$$  

Proof. Since $B^T B$ is a real symmetric matrix, its eigenvalues are real. Moreover, for any $x \in \mathbb{C}^N$, we have $(B^T B x, x) = (B x, B x) \geq 0$, so these eigenvalues are nonnegative. We have

$$\eta = \max\{(B^T B x, x) : x \in V_0, ||x|| = 1\} = \max\{(B x, B x) : x \in V_0, ||x|| = 1\}.$$  

(34)

Now let $y \in V_0$ be an eigenvector of $BP$, corresponding to the eigenvalue $\lambda$, and normalised so that $||y|| = 1$. Then

$$|\lambda|^2 = (\lambda y, \lambda y) = (BP y, BP y) = (B z, B z),$$

where $z = P y$. But $z \in V_0$ since $P$ is column stochastic, and $||z|| = 1$ since $P$ is orthogonal, so that $|\lambda|^2 \leq \eta$ as claimed.

Now suppose that $B$ is also a circulant matrix. Let $y_j = N^{-1/2} v_j$, where the $v_j$ are as in the proof of Proposition 8.2. Then the $y_j$ for $1 \leq j \leq N - 1$ form an orthonormal basis of eigenvectors for $B$ on $V_0$. Let $\lambda_j$ be the eigenvalue for $y_j$, and let $k$ be an index such that $|\lambda_k| = \max_{1 \leq j \leq N - 1} |\lambda_j|$. For any $x \in V_0$ with $||x|| = 1$, we may write $x = \sum_{j=1}^{N-1} c_j y_j$ with $\sum_{j=1}^{N-1} |c_j|^2 = 1$. Then

$$(B x, B x) = \sum_{j=1}^{N-1} |c_j|^2 |\lambda_j|^2 \leq |\lambda_k|^2 = (B y_k, B y_k),$$

28
so the maximum in (34) is attained at \( \mathbf{x} = \mathbf{y}_k \), giving \( \eta = |\lambda_k|^2 \).

**Remark 8.5** A similar argument is used in [3] to control the spectral gaps for a special class of doubly stochastic matrices.

**Proof of Theorem 4.** For Statement 1, see Section 3.3. We now consider Statement 2.

For a given \( \sigma \in S_N \), we are interested in the eigenvalues of the matrix \( \Phi(1) = m^{-1}B(m,N)Q(\sigma) \), since these are the eigenvalues of \( \Phi(1) \) (where \( \Phi(z) \) is the Fredholm matrix of \( \sigma \circ f \)) and therefore the isolated eigenvalues in \( \text{Spec}(\mathcal{L}_f|_{BV}) \). By Lemma 8.1 it suffices to consider the eigenvalues of \( m^{-1}A(m,N)P(\sigma) \).

Since we are assuming that \( \gcd(m,N) = 1 \), the matrix \( C(m,N) \) can be obtained from \( A(m,N) \) by applying some permutation \( \tau \) to the rows. Thus \( P(\tau^{-1})A(m,N) = C(m,N) \). For any \( \sigma \in S_N \), the matrix \( m^{-1}A(m,N)P(\sigma) = m^{-1}P(\tau)C(m,N)P(\sigma) \) is conjugate to \( m^{-1}C(m,N)P(\sigma \tau^{-1}) \), so it suffices to consider the eigenvalues of the doubly stochastic matrices \( m^{-1}C(m,N)P(\sigma) \) for all \( \sigma \in S_N \). We exclude the eigenvalue 1 associated to the trivial eigenvector\( \mathbf{e} \), so consider only the eigenvalues on its orthogonal complement \( V_0 \).

We apply Lemma 8.4 to the doubly stochastic circulant matrix \( B = m^{-1}C(m,N) \). For any \( \sigma \in S_N \), and any eigenvalue \( \lambda \) of \( BP(\sigma) \) on \( V_0 \), we have \( |\lambda| \leq \sqrt{\eta} \), where, by Propositions 8.2 and 8.3

\[
\eta = \left| \frac{\sin(m\pi/N)}{m \sin(\pi/N)} \right|.
\]

We finish by noting some further consequences of Proposition 8.2

**Proposition 8.6** Suppose that \( \gcd(m,N) = 1 \). Then for any \( \sigma \in S_N \), the matrix \( A(m,N)P(\sigma) \) has eigenvalue \( m \) with (algebraic) multiplicity 1. All its other eigenvalues are algebraic integers of norm \( \pm 1 \). Composition with \( \sigma \) preserves the mixing rate of \( f \) (that is, \( \Lambda_{\sigma} = 1/m \) in the notation of Section 3.3) if and only if these algebraic integers are roots of unity.

**Proof.** Clearly the characteristic polynomial of \( A(m,N)P(\sigma) \) has integer coefficients and has leading coefficient 1, i.e. its roots are algebraic integers. If \( \lambda \) is any one of these eigenvalues, then its conjugates are also eigenvalues, and its norm (i.e. the product of its conjugates) must be a rational integer. Now the product of the eigenvalues is \( \pm \det(A(m,N)P(\sigma)) = \pm \det(C(m,N)) \det(P(\tau)) = \pm m \) since any permutation matrix has determinant \( \pm 1 \). We have the obvious eigenvalue \( m \) (with eigenvector \( \mathbf{e} \)), so \( m \) has multiplicity 1 as a root of the characteristic polynomial, and all the other roots must have norm \( \pm 1 \).

Now if all the eigenvalues \( \lambda \neq m \) of \( A(m,N)P(\sigma) \) are roots of unity, we have \( |\lambda| = 1 \). Thus no element of \( \text{Spec}(\mathcal{L}_f|_{BV}) \) has modulus between \( m^{-1} \) and 1, and \( \sigma \circ f \) has the same mixing rate as \( f \). Conversely, suppose that \( \sigma \circ f \) and \( f \) have the same mixing rate. Then we must have \( |\lambda| \leq 1 \) for all eigenvalues \( \lambda \neq m \) of \( A(m,N)P(\sigma) \). But then
all the conjugates $\lambda'$ of $\lambda$ are again eigenvalues, and hence satisfy $|\lambda'| \leq 1$. In fact each $|\lambda'| = 1$, since the product of the $\lambda'$ is $\pm 1$. Now any algebraic integer all of whose conjugates have modulus 1 must be a root of unity (see e.g. [7, IV, (4.5a)]). Hence all the eigenvalues $\lambda \neq m$ of $A(m, N)P(\sigma)$ are roots of unity.

From a purely algebraic point of interest, we make one further remark about the transition matrices.

**Remark 8.7** When $\gcd(m, N) > 1$, the matrix $A(m, N)$ has 0 as an eigenvalue. Since we recover $A(m, N)$ from $B(m, N)$ by factoring out the full nullspace of $B(m, N)$, it follows that $B(m, N)$ is not diagonalisable; it is conjugate to a matrix in Jordan Canonical Form with at least one Jordan block of size $> 1$ for the eigenvalue 0.
